

21 October 2021

Recall that a **red-black** tree satisfies the following properties:

- The root and all leaves are black
- Both children of a red node are black
- All leaves have the same black depth (black ancestors)

1. **Warm up 1:** Answer the following True / False statements.

- A subtree of a red-black tree is itself a red-black tree.
- The sibling of a leaf is either a leaf or it is red.
- Every red-black tree is an AVL (height-balanced) tree.

2. A **matching** of a tree is a subset of the edges of a tree so that no two edges share a vertex. A matching is **perfect** if every vertex of the tree is incident to exactly one edge of the matching.

- Does a complete binary tree always have a matching? Which do and which do not?
- For a binary tree of height h , what is the largest number of nodes it can have to have a perfect matching?
- For an n -ary tree of height h , what is the largest number of nodes it can have to have a perfect matching?

3. Recall the **insertion** sort, **selection** sort, **merge** sort, and **quick** sort algorithms.

- Which of these are in-place algorithms? Deterministic algorithms?
- If an input list is already sorted, which algorithm will be fastest? Slowest?
- The list below is not sorted, and both insertion and selection sort take the same number of steps to sort it. How many comparisons are done in each step?

	1	4	19	5	15	10	2	3	
	step								
	1	2	3	4	5	6	7	8	
comparisons for insertion sort									
comparisons for selection sort									

A comparison is when two elements are compared in size.

- Draw all the steps that merge sort would take on this list.
- For quick sort, which of the values are good pivots? Draw all the steps that quick sort would take on the list, if the pivot is element number $\lfloor \frac{\text{length of list}}{2} \rfloor$.
