## FINAL (SAMPLE QUESTIONS)

The actual Final exam will take place on May 13, 2022. It is held at 10:00. See https://bit.ly/3KxuMdV for the official information.

Below are some sample questions that might assist you as you prepare for the final and see the topics and ideas that are typically covered in a final. We cannot guarantee that the final exam questions will closely match these samples; but these samples may be useful as you prepare.

## **Topics**

- Time complexity of various algorithms.
- Regular hashing and building hashtables (chaining or open addressing).
- Naive string search algorithm.
- Rolling hashes and Rabin-Karp algorithm (to search one or several patterns in a text).
- KMP algorithm and prefix function.
- · Suffix trees.

**Question 1:** (Some pseudocode of an algorithm is given. The algorithm may be recursive or it may contain nested loops or calls to other functions, if their time complexity is known.) The task is the determine the overall time complexity of a single algorithm call, if the input length (or similar input-related parameters) are known.

Question 2: In this task you will draw a hashtable with open-address hashing.

To run the Python environment on Linux like this (tested on Ubuntu command-line):

```
export PYTHONHASHSEED=0 python
```

On Windows Powershell (such as Anaconda terminal) run Python environment like this:

```
$Env:PYTHONHASHSEED=0
python
```

On Windows regular terminal run Python environment like this:

```
set PYTHONHASHSEED=0
python
```

(A) Draw a hashtable with exactly 11 slots (enumerated as T[0], T[1], and so on, up to T[10]). Insert the following items into this hashtable (keys are names for countries and lands, but values are float numbers showing their population in million):

```
('Macedonia',1.8), ('Malta',0.5), ('Mecklenburg-Vorpommern',1.6), ('Moldova',2.6), ('Montenegro',0.6), ('Croatia',4.0), ('Nordrhein-Westfalen',17.9), ('Norway',5.4)
```

If there are any collisions between the hash values, add the additional hash values to a linked list using *chaining*. Each item in the linked list contains a key-value pair and also a link to the next item.

**(B)** What is the expected lookup time, if we randomly search any of the 8 lands to look up its population. Finding an item in a hash table takes 1 time unit; slipping by one slot ahead also takes 1 time unit.

**Question 3:** Consider 16 Latin letters with randomly assigned 4-bit codes (i.e. L=4):

Let-	A	В	C	D	E	F	G	Н	I	J	K	L	M	N	0	P
ter																
h(x)	1100	0100	0010	0110	0111	0000	1001	1111	0101	1101	1110	1011	0011	1010	1000	0001

(A) Find the hash value for ABIDE and then rotate it over to BIDEN. Please recall that the rolling hash uses the following formula:

$$H = s^{k-1}(h(c_1)) \oplus s^{k-2}(h(c_2)) \oplus \ldots \oplus s(h(c_{k-1})) \oplus h(c_k),$$

(B) Write a formula to compute skip(c, v) to skip a character from the front of the string. For example, if v1 = H("ABIDE") is the hash value for ABIDE, and v2 = H("BIDE") is the hash value for BIDE, then v2 = skip("A", v1).

Namely, show a time-efficient way to drop the first letter of the hash function argument (without recomputing the hash function value from the scratch).

(C) Write a formula to compute append (c, v) to append a new character at the end of the string. For example, if v2 = H("BIDE") and v3 = H("BIDEN"). then v3 = H("N", v2).

Namely, show a time-efficient way to add one more letter at the end of the hash function argument, (without recomputing the hash function value from the scratch).

Note: See full discussion on Cyclic Polynomial rolling hash here: https://bit.ly/3F5phlA.

**Question 4:** In the string T=879487 find the pattern P=9487. Run the Rabin-Karp algorithm (see pseudocode below). Use the values  $a=10,\,q=13$ .

```
\begin{split} &RABINKARPSTRINGMATCHING(T,P,a,q)\\ &rP = ROLLINGHASH([])\\ &for\ i\ \mathbf{n}\ RANGE(0,len(P)):\\ &rP.\mathsf{APPEND}(P[i])\\ &rT.\mathsf{APPEND}(T[i])\\ &for\ i\ \mathbf{n}\ RANGE(len(P),len(T)):\\ &\mathbf{if}\ rP.\mathsf{HASH}() == rT.\mathsf{HASH}():\\ &(\textit{Here we need to double-check as collisions are possible})\\ &\mathbf{if}\ P = T[i-len(P)+1:i+1]\\ &\mathbf{output}\ Pattern\ found\ at\ offset,\ i-len(P)+1\\ &rT.\mathsf{SKIP}(T[i-len(P)])\\ &\mathbf{PRINT}(rT.\mathsf{HASH}()) \end{split}
```

```
rT.APPEND(T[i])
PRINT(rT.HASH())
```

In your answer specify the hash values that would be printed as you run this algorithm. The hash function that is used is remainder when divided by q = 13.

Note: See full discussion on Rabin-Karp algorithm here: https://bit.ly/3LyBnpz.

## **Question 5:**

- (A) Build the KMP (Knuth-Morris-Pratt) data structures if we need to match the pattern abababc.
- **(B)** Show how this works on the following text: T = abcababacabababac.
- (C) Draw a finite state acceptor (FSA) for the pattern.
- **Question 6:** Find the prefix function for the pattern P = abcbcab. Demonstrate how it works on the text T = abcabbcabcbcababababcbcab.
- **Question 7:** This exercise starts with building a suffix array for a short text. Then the suffix array (and its LCP information) is converted into a Cartesian tree which also serves as the suffix tree for that text. Finally that Cartesian tree is used to find a common substring that appears in the text multiple times.

**Note:** To understand Suffix trees and Suffix arrays, you can read the MIT OCW website: https://bit.ly/3IcnUCM or https://bit.ly/3EgJnrV.

- (A) Consider a text T = MALAYALAM. Its length (including the terminating dollar) is |T| = 10. Create a suffix array for this string together with the LCP information (i.e. find the longest common prefix of any two suffixes that are alphabetically next to each other).
  - Write out the suffix array and the related LCP information as two sequences (e.g. one under another). Use this alphabetical order:  $\Sigma = \{\$, \texttt{A}, \texttt{L}, \texttt{M}, \texttt{Y}\}$ . Please note that the suffix array has length |T| = 10 (all the non-empty suffixes of the text T), and the LCP information has length |T| 1 = 9.
- **(B)** Draw Cartesian tree from the sequence with LCP information. This tree should have |w| 1 = 9 internal nodes and |w| = 10 leaves. Draw internal nodes as squares and leaves as circles.
  - Label each internal node with the LCP number (the longest common prefix) and each leaf with the prefix order number (The longest prefix T[0:10] = MALAYALAM\$ has order number 0, and the shortest nonempty prefix T[9:10] = \$ has order number 9.)
- (C) Consider leaves #6 and #2 in the Cartesian tree obtained in (B). List the compressed edges on the path from the root node to these leaves. Mark the internal node that shows the longest common prefix of both suffixes: T[6:10] = LAM\$ and T[2:10] = LAYALAM\$.

## 1.1 Appendix: Banana Example

Here is an example that is similar to the above task. Please refer to the video https://bit.ly/3EgJnrV (starting from 1:10:00). A drawing from the video shows suffix array for text T = BANANA\$, and related LCP information (red numbers to the left of the suffix array). The central part of the drawing is a Cartesian tree built from this suffix array and its LCP information. On the right is the suffix tree (with compressed edges, where just the branching nodes and leaves are shown). The suffix tree should have the same shape as the Cartesian tree, but its edges are labeled with one or more letters from alphabet  $\Sigma$ .

Consider two leaves with numbers #4 and #2 (the corresponding prefixes are T[4:7] = NA\$ and T[2:7] = NANA\$).

The (compressed) paths to these leaves are:

```
{ Path to the leaf #4: ["NA","$"] Path to the leaf #2: ["NA","NA$"]
```

The longest common prefix of these two suffixes (i.e. the nearest ancestor of the two leaves in the suffix tree) is shown in Fig.1.

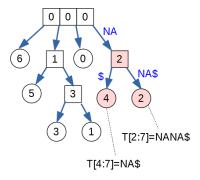

Fig. 1: The Cartesian tree for the prefixes of text T = BANANA\$.

The pink square (internal node labeled by 2) corresponds to the substring NA. The label for the square-shaped internal node indicates that the common substring NA has length 2.

**Note:** The Cartesian tree in Fig.1 shows 3 internal nodes that are drawn together and have 4 branches: The root of the tree (the state before receiving any input) can continue with any of the four letters: \$, A, B, N – at this point we do not know which location of BANANA\$ text will be searched.
